

Forensic Anthropology

Dr Laura Sinfield

L.N.Sinfield@ed.ac.uk

Forensic Anthropology

- In the UK, most commonly used for identification of human remains which have not been identified by other methods
- Can also be used to aid in identifying cause of death
- In the UK in recent years, most commonly carried out by forensic anthropologist
- In rest of Europe and in past in UK, carried out by forensic pathologists, etc.

Tool-marks

Saw-
type

Knife-
type

Cranial fractures - radiating

- Near-instantaneous
- Unable to cross an existing fracture-line

Order of defects (a)

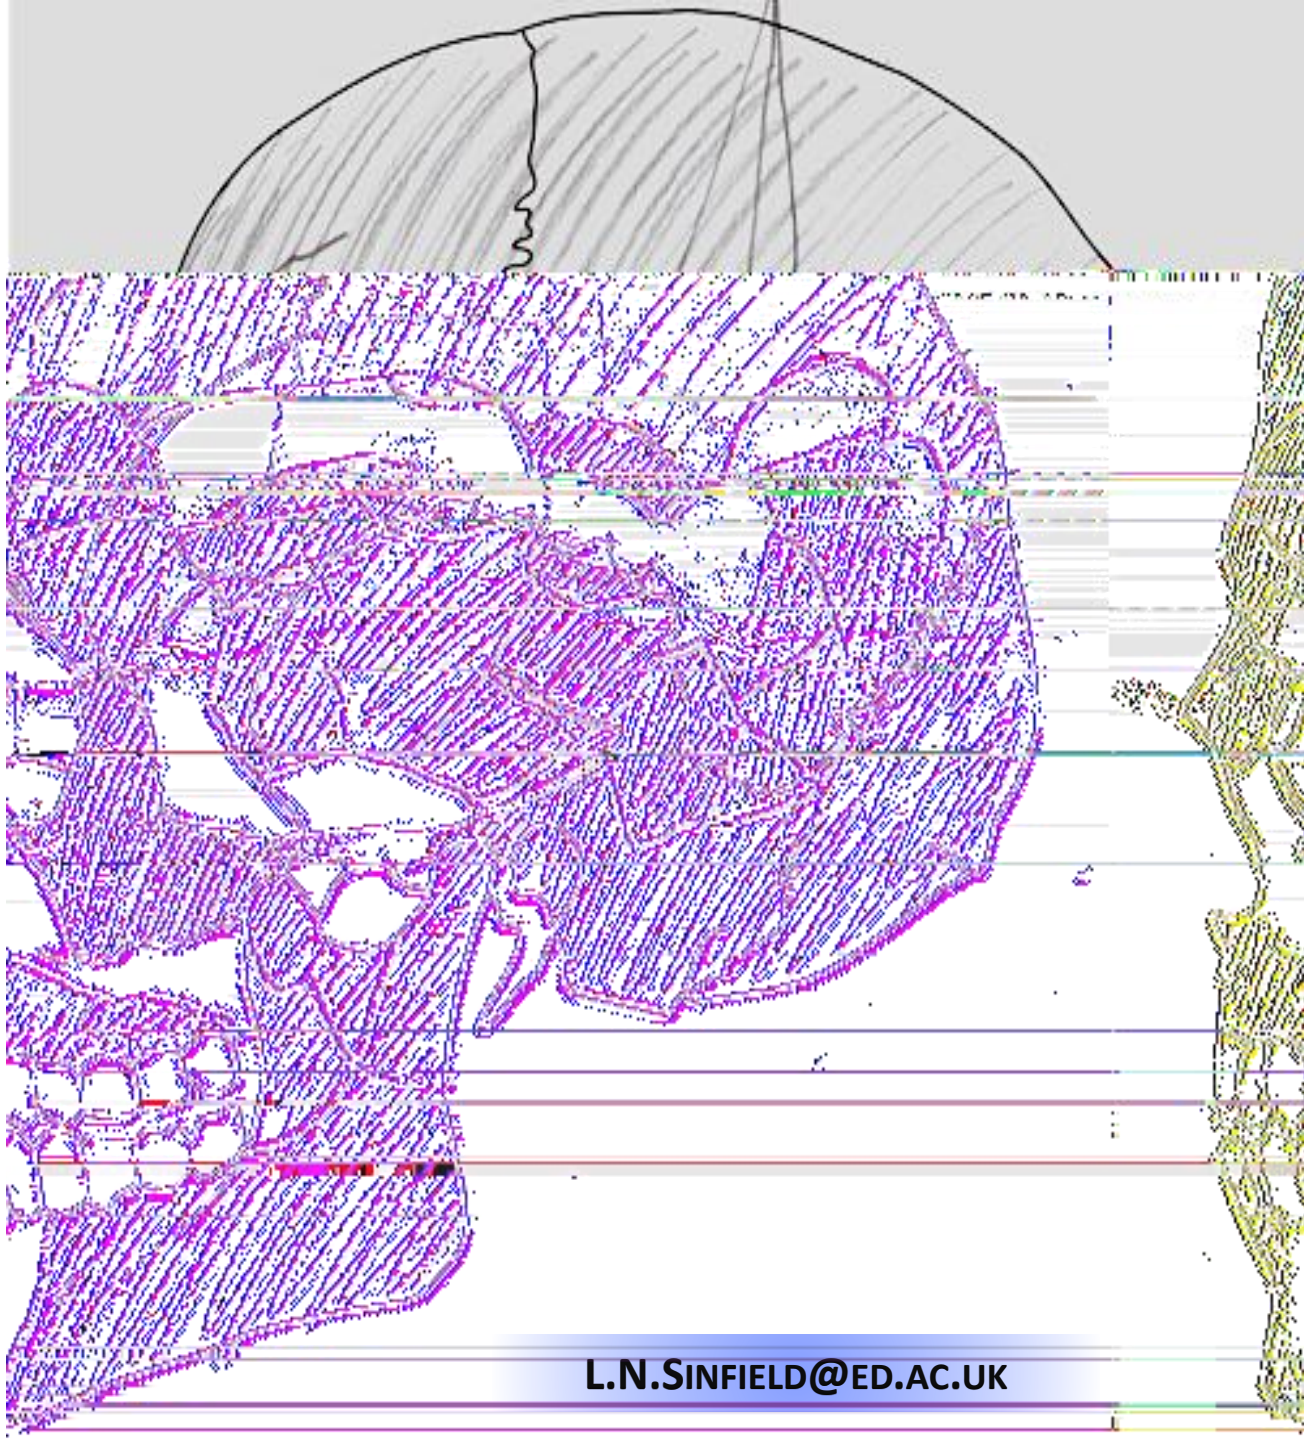

Order of defects (b)

(Not the case in next slide, but similar)

Cause of Death – and an indicator of Manner of Death

Thin Section

- No need for de-calcification in some circumstances
- Fast and simple

Osteon Counting: Thin Section Preparation

Forensic histology & bone

- Species differentiation
 - Primate/non-primate
 - Human/other primate
- Age estimation
 - Osteon counting
- Post mortem interval
- Bony response to injury

Osteons and socio-economic status

- Keough et al FSInt 2009
- Osteon:age relationship may be affected by socio-economic status
- Call for ‘databank’ of known-individual samples to be built up

Histology & Injury response

- Histological signs of bony response to injury – especially in children
- Cattaneo et al ‘The Detection of Microscopic Markers of Hemorrhaging and Wound Age on Dry Bone: a Pilot Study’ AJFMP 2010 31(1):22-26
- “A total of 6 samples of fractured bone (cranium, rib, and tibia) were taken from cadavers with known time of survival between trauma and death. Time intervals ranged from a few seconds after the bone fracture had been inflicted, to several hours, days, and weeks. A negative control was included (postmortem fracture)”
